Imidazole Derivatives as MDR Modulators

This is a continuation-in-part application of our co-pending application serial No 08/890911 filed on July 09, 1997, the disclosure of which is incorporated herein by reference.

FIELD OF THE INVENTION

The present invention provides novel imidazole derivatives, novel pharmaceutical compositions containing same, methods of their use, and methods of their manufacture. Such compounds are pharmacologically useful for restoring the sensitivity of multidrug resistant cells to cancer chemotherapeutic agents.

BACKGROUND OF THE INVENTION

A major problem in the treatment of cancer is the emergence of tumor cell resistance to chemotherapeutic agents and the subsequent patient relapse (Bradley *et al.*, *Cancer Res.* 1989, 49, 2790-2796; Raderer and Sscheitharer, *Cancer* 1993, 72, 3553-3563). These cancer victims may fail to respond to any antitumor agent, since these tumor cells tend to exhibit clinical resistance to many drugs. This phenomenon is known as multi-drug resistance (MDR). MDR is associated with certain alterations in tumor cells resulting in reduced intracellular anticancer drug accumulation, including reduced membrane permeability and increased removal of drug from the cell *via* an energy-dependent efflux mechanism. Studies of this mechanism have led to the characterization of genes capable of conferring resistance to chemotherapeutic agents. One of these genes, the P-glycoprotein or MDR1 gene, has been strongly implicated since overexpression of this gene can lead to resistance to anthracyclines, vinca alkaloids, and podophyllins, all important chemotherapeutic agents. MDR1 encodes a 170 kDa membrane glycoprotein (gp-170 or Pgp) that acts as an ATP-dependent efflux pump, transporting a number of unrelated organic compounds out of the cell (Juranka *et al.*, *FASEB J.* 1989, 3, 2583-2592). The level of expression of gp-170 has been shown to correlate with the degree of drug resistance (Raderer and Sscheitharer, *Cancer* 1993, 72, 3553-3563). Gp-170 appears to act as a pump that actively extrudes a wide variety of structurally unrelated compounds, including a full range of antineoplastic drugs. Another ATP-dependent membrane efflux pump, the product of the MRP gene, has also been implicated in the MDR phenomenon (Krishnamachary and Center, *Cancer Res.* 1993, 53, 3658-3661), as have other

ATP-dependent and enzymatic mechanisms.

Drugs of proven antitumor chemotherapeutic value to which MDR has been observed include vinblastine, vincristine, etoposide, teniposide, doxorubicin (adriamycin), daunorubicin, pliamycin (mithramycin), and actinomycin D (Jones *et al.*, *Cancer (Suppl)*1993, 72, 3484-3488). Many tumors are intrinsically multi-
5 drug resistant (e.g., adenocarcinomas of the colon and kidney) while other tumors acquire MDR during the course of therapy (e.g., neuroblastomas and childhood leukemias).

A variety of structurally diverse agents have been identified which can
10 restore partly or sometimes completely the normal drug sensitivity to some MDR tumor cells. It is assumed that these chemosensitizers are effective as a result of their ability to interfere with gp-170, causing a reversal in the increase in drug efflux. Among these agents are calcium channel blockers (e.g., verapamil), calmodulin inhibitors (e.g., trifluoperazine), antibiotics (e.g., erythromycin),
15 cardiovascularagents (e.g., quinidine), noncytotoxic analogs of anthracyclines and vinca alkaloids, cyclosporin A and analogs thereof, FK-506 and analogs thereof, and derivatives of cyclopeptides (Lum *et al.*, *Cancer (Suppl)*1993, 72, 3502-3514). However, at the present time, none of these agents has provided a significant contribution to the chemotherapeutic index for the treatment of
20 cancer due to their significant pharmacological effects on other organ systems. An effective therapeutic agent for the reversal of MDR needs to have efficacy against the membrane pump as well as lack of significant toxicity and other non-specific pharmacological effects.

The present invention describes a family of novel substituted imidazole
25 derivatives of Formula (1) that are effective in increasing the sensitivity of tumor cells resistant to anticancer chemotherapeutic agents, such as doxorubicin (DOX), taxol, vinblastine (VLB), and enhancing the sensitivity of multi-drug resistant cells. These compounds have the effect of reducing the resistance of MDR tumor cells, and potentiating the sensitivity of cells to antitumor drugs,
30 such as DOX, taxol, VLB. These compounds are expected to have broad application in the chemotherapy of cancer.

SUMMARY OF THE INVENTION

The novel compounds of this invention have the general structure (1)

Formula 1

and are capable of restoring sensitivity to multi-drug resistant tumor cells. It is
 5 an object of this invention to provide compounds that have sufficient activity to
 sensitize multi-drug resistant tumor cells to antineoplastic agents.

It is an additional object of this invention to provide a method of
 sensitizing multi-drug resistant tumor cells using the novel compounds of the
 present invention.

10 A further object is to provide a method of treatment of MDR or drug-
 sensitive tumor cells by administering a sufficient amount of a compound of the
 present invention, prior to, together with, or subsequent to the administration of
 an antitumor chemotherapeutic agent. A further object is to provide
 pharmaceutical compositions for increasing the sensitivity of tumor cells to
 15 antitumor chemotherapeutic agents and thus for the treatment of tumors that
 are susceptible to anti-cancer chemotherapeutic agents but have become
 resistant to such chemotherapy.

The procedures employed to synthesize compounds depicted in Formula 1 are as follows:

Method A. General Procedure for the Preparation of Diones:

There are three methods by which these diones were synthesized, namely:

Method 1

4,4'-difluorodione **1** was reacted with a series of amines ($\text{R}_1\text{R}_2\text{NH}$) using an appropriate base such as K_2CO_3 , Na_2CO_3 , Et_3N , diisopropylethylamine (DIEA), etc., at elevated temperature ($60\text{--}150^\circ\text{C}$) in an appropriate solvent such as alcohol, acetonitrile, N,N -dimethylformamide (DMF), dimethylsulfoxide (DMSO) to provide the mono-amino-diones **2** (procedure Bader et al *J. Org. Chem.* 1966, 31, 2319). The mono-amino-diones **2** were further reacted with another amine ($\text{R}_3\text{R}_4\text{NH}$) under the same conditions to afford the desired diones **3** as shown in Scheme 1. This procedure allows for the synthesis of unsymmetrical diones **6** (wherein $\text{R}_1\text{R}_2\text{NH}$ is different from $\text{R}_3\text{R}_4\text{NH}$). This chemistry was carried out using 1-1.5 equivalent of $\text{R}_1\text{R}_2\text{NH}$ and upon the completion of the reaction another equivalent of different amine ($\text{R}_3\text{R}_4\text{NH}$) was added to the reaction mixture to provide the desired unsymmetrical diones (Scheme 1).

Scheme 1

Unsymmetrical diones were prepared according to the following procedure: To a solution of 4,4'-difluorobenzil in DMSO (0.5 M) was added 1.2 equiv of amine R_1R_2NH and 2 equiv of potassium carbonate. The resulting mixture was stirred in a 90°C oil bath for 6-15 hours (TLC monitoring). After completion, the mixture was diluted with ether and extracted with 3 M hydrochloric acid (x5) to remove the small amount of product resulted from the di-displacement. The organic layer was then washed with 6 M hydrochloric acid until no more desired product in the ether layer (5 times). The aqueous layer was neutralized to pH 8 with 6 M aqueous sodium hydroxide and it was extracted with dichloromethane. The organic layers were dried (Na_2SO_4), evaporated to give 4-amino,4'-fluorobenzil. This procedure was repeated with the second amine R_3R_4NH (normally 2-3 equiv) and a simple workup by diluting the reaction mixture into ether and washed with water to remove DMSO. 4,4'-diaminobenzil was thus obtained (50-90% overall depending amines used) in high purity.

For symmetrical diones (wherein R_1R_2NH is equal to R_2R_3NH) the following procedure was followed:

To a solution of 4,4'-difluorobenzil in DMSO (0.5 M) was added 2-3 equiv of amine R_1R_2NH and 2-3 equiv of potassium carbonate. The resulting mixture was stirred in an 90°C oil bath for 6-15 hours (TLC monitoring). After completion, the mixture was diluted into ether and washed with water to remove DMSO. The desired diones 6 were obtained (50-90% overall depending amines used) in high purity. The following examples have been synthesized according to method 1:

The crude material thus obtained was dissolved in dichloromethane (DCM, 100.0 mL) and cooled to -78°C . DIBAL-H (1.0 M in DCM, 45 mL, 45 mmol) was added over 20 min. Aqueous NaOH (1.0 M, 100 mL) was added and the mixture was warmed to room temperature (23°C) and the layers were separated. The aqueous layer was extracted with DCM (X3), and the combined organic layers were dried (Na_2SO_4) and evaporated. Flash chromatography of the residue over silica gel gave the desired allylic alcohol **37**. Compound **37** has: ^1H NMR (400 MHz, CDCl_3) δ 4.00 (d, 2H), 4.10 (m, 2H), 4.30 (d, 2H), 6.35 (dt, 1H), 6.60 (d, 1H), 7.48 (m, 4H).

Method C. General Procedure for the Preparation of Imidazoles:

Method 1

Imidazoles **55** were synthesized according to modified literature procedure (Krieg et al *Z Naturforsch teil* 1967, 22b, 132).

20 The proper dione (3.04 mmol.) and aldehyde (4.56 mmol.) were placed in acetic acid (5.85 mL) and ammonium acetate (30.4 mmol.) was placed in acetic acid (1.75 mL) in a separated reaction flask. Both of the flasks were heated in an preheated oil bath (140°C). As soon as the solids in the two flasks were
 25 dissolved, poured the hot solution of ammonium acetate in acetic acid into the other flask which contains the aldehyde and dione. The resulting mixture was heated at 140°C for 40 min. It was then cooled to room temperature. The pH of solution was adjusted to 0.8 using 3.0 M hydrochloric acid. It was then extracted with ether (5 times) to remove the unreacted aldehyde and dione). The

aqueous layer was neutralized to pH 8 with 3 M sodium hydroxide and extracted with methylenechloride (3 times). The organic layers were dried (N_2SO_4) and evaporated to give the corresponding imidazole compound.

Method C-2

Imidazoles of this type were synthesized in the following way:

The appropriate substituted phenylglyoxal and aldehyde (equal molar amount to the phenylglyoxal) were stirred in methanolic ammonia at room temperature (TLC monitored). At completion, the reaction mixture diluted with ethyl acetate and washed with water (X2). The organic layer was then washed with hydrochloric acid (2N) until no more desired compound in the organic layer. The aqueous layer was then neutralized with aqueous NaOH (2 N), and extracted with CH₂Cl₂ (X2). The organic layer was dried (Na₂SO₄) and evaporated. Further chromatographic purification then gave the desired compound. The following compounds were synthesized in this way:

10 The compounds described herein are capable of sensitizing multi-drug resistant tumor cells to antitumor chemotherapeutic agents, such as doxorubicin and vinblastine. They also have the ability to potentiate the sensitivity of tumor cells susceptible to these chemotherapeutic agents. This invention also relates to a method of sensitizing multidrug-resistant tumor cells to antitumor
15 chemotherapeutic agents. It also relates to a method of increasing the sensitivity of drug-susceptible tumor cells to antitumor chemotherapeutic agents. In addition, this invention relates to a method of preventing the emergence of MDR tumor cells during a course of treatment with antitumor chemotherapeutic agents. Finally, this invention relates to a method of reducing the effective
20 dosage of an antitumor chemotherapeutic agent during a course of treatment. It has been found that compounds of Formula 1 have the ability to increase the sensitivity of MDR mammalian cells in culture.

 Cytotoxic drugs are commonly used as antitumor chemotherapeutic agents. These agents are also called antiproliferative agents. The desired effect
25 of cytotoxic drugs is selective cell death with destruction of the malignant neoplastic cells and relative sparing of normal cells.

 Cytotoxic drugs have also proved valuable in the treatment of other neoplastic disorders including connective or autoimmune diseases, metabolic disorders, dermatological diseases, and DNA virus infections.

Proper use of cytotoxic drugs requires a thorough familiarity with the natural history and pathophysiology of the disease before selecting the cytotoxic agent, determining a dose, and undertaking therapy. Each patient must be carefully evaluated, with attention directed toward factors which may potentiate toxicity, such as overt or occult infections, bleeding dyscrasias, poor nutritional status, and severe metabolic disturbances. In addition, the functional condition of certain major organs, such as liver, kidneys, and bone marrow, is extremely important. Therefore, the selection of the appropriate cytotoxic agent and devising an effective therapeutic regimen is influenced by the presentation of the patient.

Cytotoxic drugs as antitumor chemotherapeutic agents can be subdivided into several broad categories, including, (1) alkylating agents, such as mechlorethamine, cyclophosphamide, melphalan, uracil mustard, chlorambucil, busulfan, carmustine, lomustine, semustine, streptozotocin, and decrabazine; (2) antimetabolites, such as methotrexate, fluorouracil, fluorodeoxyuridine, cytarabine, azarabine, idoxuridine, mercaptopurine, azathioprine, thioguanine, and adenine arabinoside; (3) natural product derivatives, such as vinblastine, vincristine, dactinomycin, daunorubicin, doxorubicin, mithramycin, bleomycin, etoposide, teniposide, and mitomycin-C; and (4) miscellaneous agents, such as hydroxyurea, procarbazine, mititane, and cis-platinum.

Important antitumor chemotherapeutic agents (with the usual effective dosage) to which clinical multidrug-resistance has been observed include vinblastine (0.1 mg per kilogram per week), vincristine (0.01 mg per kilogram per week), etoposide (35 to 50 mg per square meter per day), dactinomycin (0.15 mg per kilogram per day), doxorubicin (500 to 600 mg per square meter per week), daunorubicin (65 to 75 mg per square meter per week), and mithramycin (0.025 mg per kilogram per day). MDR has been shown to occur *in vitro* as well as in the clinic.

Multidrug-resistant cell lines are easily obtainable for *in vitro* determination of drug sensitization by compounds of the present invention. *In vitro* potentiation of antineoplastic cytotoxicity by the imidazole derivatives of the present invention was measured in both CEM/VLB1000 and SK/VLB1000 cell lines. The multidrug resistant cell lines were obtained from Dr. Victor Ling, Ontario Cancer Institute, Toronto, Canada. The CEM/VLB 1000 cell line was maintained as a suspension in minimum essential medium supplemented with 10% fetal bovine serum in a humidified atmosphere of 95% air and 5% CO₂ while the SK/VLB 1000 cell line was maintained as adherent cells using the identical medium conditions as the CEM cells. The CEM/VLB 1000 cells were seeded at a

density of 5×10^4 cells/well in a 96 well microtiter plate while the SK/VLB 1000 cell line was seeded at a density of 2,500 cells/well after trypsinization.

Vinblastine (5 $\mu\text{g/mL}$, for the CEM cells) or Taxol (3 $\mu\text{g/mL}$, for the SK cells) and compound (0.01 to 50 μM) were added directly to the wells. After an incubation of 48 hours in presence of drug, alamar blue (B. Page et al., *Int. J. Oncol.* 3: 473-476, 1993) was added (10 μL to the 200 μL cell suspension) for a period of 24 hours after which the fluorescence (excitation = 530 nm, emission = 590 nm) was read for each well using a "CytoFluor" microtiter fluorometer plate reader. This assay measures the effective concentration of compound necessary to enhance the cytotoxicity (EC_{50}) of vinblastine in the MDR cell line. The compounds of the present invention had EC_{50} values in the range of 0.06 to 10 μM .

^3H -vinblastine accumulation was also measured in the CEM/VLB1000 cell line. Corning Easy-Wash 96 well plates were pretreated with PBS and 1% BSA for 60 minutes and then removed. CEM/VLB1000 cells were seeded at 2×10^5 , 40 μL volume. Plates were incubated at 37°C for 30-60 minutes prior to use. The reference reversing agent, verapamil, or the compound of the present invention was added to the well followed by addition of media containing ^3H -vinblastine (final concentration = 275 nM). Plates were allowed to incubate for 3 hours at 37°C . Cells were harvested onto pretreated Wallace filtermats A (pretreated with 0.1% polyethyleneimine) using a TomTek harvester-96. After filtering, the filtermats were allowed to dry completely. Meltix B scintillant was then added to the filtermats. The filters were then placed in a 90°C oven for approximately 3-5 minutes and then removed. Scintillant was allowed to solidify on the filtermats. Filtermats were then placed in sample bags and read on a Wallace BetaPlate scintillation counter. The effects of compounds of the present invention in the cytotoxicity potentiation assays and vinblastine (VLB) accumulation assay are given in the Table below:

These excipients may be, for example, (1) inert diluents, such as calcium carbonate, lactose, calcium phosphate or sodium phosphate; (2) granulating and disintegrating agents, such as corn starch or alginic acid; (3) binding agents,

such as starch, gelatin or acacia; and (4) lubricating agents, such as magnesium stearate, stearic acid or talc. These tablets may be uncoated or coated by known techniques to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate may be employed. Coating may also be performed using techniques described in the U.S. Patent Nos. 4,256,108; 4,160,452; and 4,265,874 to form osmotic therapeutic tablets for control release.

Formulations for oral use may be in the form of hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, for example, calcium carbonate, calcium phosphate or kaolin. They may also be in the form of soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, such as peanut oil, liquid paraffin or olive oil.

Aqueous suspensions normally contain the active materials in admixture with excipients suitable for the manufacture of aqueous suspension. Such excipients may be (1) suspending agent such as sodium carboxymethyl cellulose, methyl cellulose, hydroxypropylmethylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia; (2) dispersing or wetting agents which may be (a) naturally occurring phosphatide such as lecithin; (b) a condensation product of an alkylene oxide with a fatty acid, for example, polyoxyethylene stearate; (c) a condensation product of ethylene oxide with a long chain aliphatic alcohol, for example, heptadecaethylenoxycetanol; (d) a condensation product of ethylene oxide with a partial ester derived from a fatty acid and hexitol such as polyoxyethylene sorbitol monooleate, or (e) a condensation product of ethylene oxide with a partial ester derived from fatty acids and hexitol anhydrides, for example polyoxyethylene sorbitan monooleate.

The pharmaceutical compositions may be in the form of a sterile injectable aqueous or oleagenous suspension. This suspension may be formulated according to known methods using those suitable dispersing or wetting agents and suspending agents which have been mentioned above. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

A compound of Formula 1 may also be administered in the form of suppositories for rectal administration of the drug. These compositions can be prepared by mixing the drug with a suitable non-irritating excipient which is solid at ordinary temperature but liquid at the rectal temperature and will therefore melt in the rectum to release the drug. Such materials are cocoa butter and polyethylene glycols.

The compounds of the present invention may also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles, and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine, or phosphatidylcholines.

For topical use, creams, ointments, jellies, solutions or suspensions, etc., containing the compounds of Formula 1 are employed.

Dosage levels of the compounds of the present invention are of the order of about 0.5 mg to about 100 mg per kilogram body weight, with a preferred dosage range between about 20 mg to about 50 mg per kilogram body weight per day (from about 25 mg to about 5 gms per patient per day). The amount of active ingredient that may be combined with the carrier materials to produce a single dosage will vary depending upon the host treated and the particular mode of administration. For example, a formulation intended for oral administration to humans may contain 5 mg to 1 g of an active compound with an appropriate and convenient amount of carrier material which may vary from about 5 to about 95 percent of the total composition. Dosage unit forms will generally contain between from about 5 mg to about 500 mg of active ingredient.

It will be understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination and the severity of the particular disease undergoing therapy.

In addition, some of the compounds of the instant invention may form solvates with water or common organic solvents. Such solvates are encompassed within the scope of the invention.

The following Examples are intended to illustrate the preparation of compounds of Formula 1, and as such are not intended to limit the invention as set forth in the claims appended thereto. Furthermore, the compounds described in the following examples are not to be construed as forming the only

genus that is considered as the invention, and any combination of the compounds or their moieties may itself form a genus. The structure and purity of all final products were assured by at least one of the following methods: thin-layer chromatography (TLC), mass spectroscopy, nuclear magnetic resonance (NMR) spectroscopy, or combustion analysis. NMR data is in the form of delta (δ) values for major diagnostic protons, given in parts per million (ppm) relative to tetramethylsilane (TMS) as internal standard, determined at 400 MHz in deuteriochloroform (CDCl_3); conventional abbreviations used for signal shape are: s, singlet; d, doublet; t, triplet; m, multiplet; br., broad; etc. The following abbreviations have also been used: v (volume), w (weight), L (liter), mL (milliliter), g (gram), mg (milligram), mol (moles), mmol (millimoles), equiv (equivalents).
